

PROJECT PROFILE

- The web application 3ChatBots is a lightweight evaluation tool that allows a user to submit one prompt and compare responses from up to 3 LLMs in a side-by-side, real-time comparison. The system has a Django template frontend and a Django REST backend API. The UI is simple with the orchestration and logic staying behind API endpoints. Model calls are encapsulated in a service layer in the backend that uses Hugging Face Inference APIs, which returns the response schema to the frontend. Implementation followed an agile, sprint-based approach. In Sprint 1, there was a definition of requirements and UI mockup as well as architecture planning. In Sprint 2, there was Django development for the frontend and backend. Sprint 3 involved integrating the LLM service from Hugging Face and refining the comparison UI. Sprint 4 was centered around containerization with Docker. Key risks are mitigated by isolating dependencies, using clear error messages and increasing timeouts, as well as treating prompts as sensitive data with minimal logging. Testing combines unit tests for serializers, API tests for the prompt-response pipeline, and HTTP status checks.
